

**Problem 3):** Since  $\mathbb{Z}_p^* \equiv \{a \in \{1, 2, \dots, p-1\} \mid \gcd(a, p) = 1\}$ , for any  $p \in \mathbb{Z}^+$ , the set of possible elements for  $\mathbb{Z}_{p^e}^*$  is defined as

$$\mathbb{Z}_{p^e}^* \subset \{1, 2, \dots, p^e - 1\} \quad (3.1)$$

This implies the following relation between the cardinalities of these sets

$$|\mathbb{Z}_{p^e}^*| < |\{1, 2, \dots, p^e - 1\}|,$$

where  $|\{1, 2, \dots, p^e - 1\}|$  has the value  $|\{1, 2, \dots, p^e - 1\}| = (p^e - 1)$ . It follows that the value of  $|\mathbb{Z}_{p^e}^*|$  can be obtained by determining the set of all values in  $\{1, 2, \dots, p^e - 1\}$  that do not satisfy the condition given in 3.1 and subtracting the cardinality of this set from  $(p^e - 1)$ . Since the common multiple is  $p$ , we will write this set in terms of  $p$ . Thus, the set of values in  $\{1, 2, \dots, p^e - 1\}$  that do not satisfy the condition in 3.1 may be defined as

$$\{p, 2p, 3p, \dots, pp, 2pp, 3pp, \dots, p^2p, \dots, (p^{e-1} - 1)p\}$$

This definition arises because only multiples of  $p$  do not satisfy the condition in 3.1 and because  $(p^{e-1} - 1)p = p^e - p$  is the largest element of  $\{1, 2, \dots, p^e - 1\}$  that does not satisfy the condition in 3.1. The cardinality of this set,  $\{p, 2p, 3p, \dots, pp, 2pp, 3pp, \dots, p^2p, \dots, (p^{e-1} - 1)p\}$  is clearly

$$|\{p, 2p, 3p, \dots, pp, 2pp, 3pp, \dots, p^2p, \dots, (p^{e-1} - 1)p\}| = (p^{e-1} - 1)$$

Subtracting this value from  $|\{1, 2, \dots, p^e - 1\}| = (p^e - 1)$  finally yields

$$\phi(p^e) = (p^e - 1) - (p^{e-1} - 1) = p^e - 1 - p^{e-1} + 1 = p^e - p^{e-1} = p^{e-1}(p - 1)$$

as desired.

To show that

$$\phi(pq) = \phi(p) \phi(q)$$

holds for any relatively prime  $p$  and  $q$ , we apply a similarly strategy to the one used above. The number of possible elements of  $\mathbb{Z}_{pq}^*$  is  $pq - 1$ . As before, we must take into account that some possible elements of  $\mathbb{Z}_{pq}^*$  will not satisfy the definition in 3.1. If we subtract the number of these elements, then we will have  $\phi(pq) = |\mathbb{Z}_{pq}^*|$ . Since there are  $p - 1$  multiples of  $q$  that do not satisfy the condition in 3.1, we must subtract  $p - 1$  from  $pq - 1$ . Similarly, since there are also  $q - 1$  multiples of  $p$  that do not satisfy the same condition, we must also subtract  $q - 1$  from  $pq - 1$ . Carrying out these subtractions gives

$$\begin{aligned} \phi(pq) &= (pq - 1) - (p - 1) - (q - 1) \\ &= pq - 1 - p + 1 - q + 1 \\ &= pq - p - q + 1 \\ &= (p - 1)(q - 1) \\ &= \phi(p) \phi(q) \end{aligned}$$

since  $\phi(p)$  and  $\phi(q)$  are defined as  $\phi(p) = p - 1$  and  $\phi(q) = q - 1$ , respectively.

We will now use the previous result to show that, for an integer  $N = \prod_i \{p_i^{e_i}\}$  and  $p_i$  distinct primes, we have

$$\phi(N) = \prod_i \{p_i^{e_i-1} (p_i - 1)\}$$

To begin, we substitute  $N = \prod_i \{p_i^{e_i}\}$  for  $N$  in the previous expression. This gives

$$\phi(N) = \phi\left(\prod_i \{p_i^{e_i}\}\right)$$

Using the result  $\phi(pq) = \phi(p) \phi(q)$ , we have

$$\phi(N) = \prod_i \{\phi(p_i^{e_i})\}$$

Finally, we apply the result  $\phi(p^e) = p^{e-1}(p-1)$  to obtain

$$\phi(N) = \prod_i \{p_i^{e_i-1}(p_i-1)\}$$

as expected.
